Kostal Smart Energy meter

Pros:

- Use RAUC Safe and Secure OTA Updates for Embedded Linux.
- Web server use stable version of Nginx 1.15.7 which currently have no publicly known vulnerabilities.
- Stable implementation of authentication token (JWT)
- Was not found some vulnerabilities by Greenbone OpenVAS, Nikto, Burp suite (incl. spider and burp intruder testing) and OWASP ZAP.

Cons:

- By default use HTTP instead of HTTPS
- No force redirect to HTTPS version
- Use self-signed TLS certificate.
- In time if user use HTTP (or do not add device certificate to trusted storage) MITM attack in conjunction with ARP spoofing can be easily implemented to intercept password which was shown on our master class (probably hacker will get access to admin panel, but will not be able to get shell on device)

+

 Some comments for our questions

 Only user documentation and marketing materials

Landis+Gyr E470

Features:

- Communications using DLMS/COSEM over the Wide Area Network (WAN) to a Head End System (HES)
- 'Over the Air' firmware upgrades.
- Standard meter, power fail, fraud detection and contractor control event logs;
- ZigBee Smart Energy Profile to communicate with other devices such as an In Home Display Unit and for communication with the External Communications Hub via a Home Area Network (HAN)
- Capable of showing messages from the utility on the meter display.

Attack ideas (motivated by known vulnerabilities in certain DLMS/COSEM implementations):

- Open source fuzzer ValiDLMS
- Security Downgrade
- Vulnerable Authentication Methods.
- Possibility to manipulate the security byte of messages

• Etc.

Landis+Gyr E470 testing

Ports:

- GPRS WAN communication for DLMS/COSEM
 - Use R&S CMW500 Wideband Radio Communication Tester
- optical interface IEC 62056-21
 - Use weidmann-elektronik USB infrared read/write head
 - Try different software/libs and initial codes
- ZigBee interface
 - Use CC2351 with alternative firmware

Zigbee USB Dongle

German SMGW's and smart meters acquisition

PPC SMGW testing

Pros:

- Was not found some vulnerabilities by Greenbone OpenVAS, Nikto, Burp suite (incl. spider and burp intruder testing) and OWASP ZAP.
- Minimalistic web server (not so much possibilities for user input = not so much things to test).
- Stably react on all tested exploits including TLS certificates with buffer overflow.
- Was not found some problems with fuzzing

Cons:

- Slow CGI (common gateway interface) based web server.
- Was found SSH server with possibility of password authentication and vulnerable for user enumeration (but by our data it is presented only in the test firmware)
- Exploit for this vulnerability was checked on the same version of software running in raspberry pi, which later allow to get a list of user names from SMGW.
- SSH password brute force was unsuccessful even with known usernames

Conexa SMGW testing

Pros:

- Even more minimalistic web server than in PPC SMGW.
- Was not found some vulnerabilities by Greenbone OpenVAS, Nikto, Burp suite (incl. spider and burp intruder testing) and OWASP ZAP.
- Stably react on all tested exploits including TLS certificates with buffer overflow.
- HKS3 does not accept other authentication methods.
- Have an additional TCP-Wrapper security mechanism which makes fuzzing more complicated. (after some numbers of incorrect TLS connections stop responding before SMGW reboot).
- Was not found some problems with fuzzing.

Cons:

Was not found during our testing

Abmelden

Der Seibsttest benötigt einige Minuten, die Ergebnisse werden in das Log eingetragen und können dort eingesehen werden.

About fuzzing and fuzzers

Advantages of our TLS fuzzer

How to understand that something wrong?

We do not have access to testing device shell, but we are able to check:

- Device Web server does not respond
- Device TLS server acts different in comparison with other TLS servers
- Device TLS server does not respond
- Device does not respond on TCP layer
- Physical interface is down / non-standard LEDs blinking

LEDs blinking described in user manual. Use python OpenCV script to automatize.

Problems:

- No fully understanding what's going on because no shell
- Testing speed

Solution – Run locally. To be able to run locally – need to get implementation and version.

How work our TLS fingerprinting approach?

Stimulation message

TLS doppelganger software

Current results

- A comparative security analysis was done.
- No critical vulnerabilities were found in the tested devices.
- Created TLS Doppelganger software, which generates Docker images of different versions of different TLS implementations with required TLS parameters.
- Created TLS fingerprinting software.
